Working with Operands and Variables

Prof. Ryan Robucci

Some Selected Material From:
http://www.asic-world.com/verilog/operators1.html
http://www.asic-world.com/verilog/operators2.html
Data Types: Nets and Variables

Nets: Provide structural connectivity, its value is determined by connection or continuous assignment.

Variables: Provide connectivity as well as ability to be assigned in a procedural block.

- reg: stores logic value
- integer: Supports Computation
- real: stores values as real numbers
- time: stores time as u64
- realtime: stores time as real

Variables where originally called registers, but since they are not actually always implemented as registers in hardware the name was changed for Verilog 2001. Take note when reading older texts.
- A variable type which can be used to abstract the hardware storage element since it remember values set in procedural code or sequential primitives – but it may also represent a node in a hardware circuit whose value is continuously set by combinatorial logic.

- It is assigned a value in Verilog by one of:
  - procedural statement
  - user-defined seq. primitive
  - task or function

- May not connect to output (or inout) ports of instantiated modules or Verilog primitives.
- May not be assigned value using a continuous assignment.
- *reg* variables are commonly used as vectors. 

```verilog
reg [msbindex:lsbindex] <varname>; 
indexes may be negative 
```

Two vector declarations with different bit-significance ordering, 
*msb-first* and *lsb-first*

```verilog
reg [31:0] regA;  // The most-significant bits are implied to be regA[31] and regB[0]
reg [0:31] regB;  // to be regA[31] and regB[0]
```

```verilog
regA = regB;  // sets regA[31] to regB[0] 
               // regA[ 0] to regB[31]
```

Bits may be **read** and **assigned** one at a time using the indexing operator [*]:

```verilog
regA[31] = regA[0]; 
```
Multiple bits may be read and assigned using the indexing operator []:

```plaintext
```

Multiple bits may be read and assigned using the indexed part-select syntax:

```plaintext
regA[0 +: 8]    // regA[7 : 0]
regB[0 +: 8]    // regB[0 : 7]
```

In general, I highly recommend always using msb-first convention as the following statement can be confusing:

```plaintext
regA[0 +: 8] = regB[0 +: 8];
```

Is the same as

```plaintext
regA[7 : 0] = regB[0 : 7];
```
Signed reg vectors and wire vectors

- reg variables and wire nets may be signed. These support signed operations like integers (integers are signed by default).

- signed reg [msb:lsb] <varname>;
  signed wire [msb:lsb] <varname>;

Ex:

  signed reg [7:0] regA;
  signed wire [7:0] wireA;

These support values -128 to 127 and the signed modifier determines different behaviors for some operations that support signed numbers.
Slides in this class may include several examples where we won't want to see all declarations crowding the slides.

Assume prefixes ur1,sr8, ur8,ur16,ur32, etc. denote unsigned variables of obvious lengths 8,16,32, etc.
Assume prefixes sr1,sr4,sr8,sr16,sr32, etc. denote signed variables of obvious lengths 1,4,8,16,32, etc.
Examples:
  reg [7:0] ur8a;
  signed reg [15:0] sr15a;

Assume prefixes uw1,sw8, uw8,uw16,uw32, etc. denote unsigned nets of obvious lengths 8,16,32, etc.
Assume prefixes sw1,sw4,sw8,sw16,sw32, etc. denote signed nets of obvious lengths 1,4,8,16,32, etc.
Examples:
  wire [7:0] uw8a;
  signed reg [15:0] sw15a;
Integers

• Generally act as a 32-bit signed value, but can be larger
• If an integer is used where a reg[31:0] is required, providing the integer can cause an implicit casting to unsigned – this interpretation of a signed storage as an unsigned can be a disaster.
• Example declaration:

```plaintext
integer int1, int2;
integer intX=100;
integer intY=10;
```
Integers as throw away variable

- In general you may use integers for named constants and as temporary throw-away variables in your code where computations assigned to integers are **computed strictly at synthesis**

- They are dangerous to use as register outputs (for which we assign using <=). Caution for other use is required.

```plaintext
integer intX=100;
integer intY=10;
integer intO=5;
integer intZ;
reg [31:0] u32q;

always @(posedge clk)
  intZ = intX/intY;  \← Can be **precomputed**
  u32q <= u32q + intZ;  \← final result is reg and designer determined that its size will hold the value in intZ this time
end
```
Unsigned Sized Literals

- When specifying numerical literals, a negative sign can denote a **two's complement operation** (one's complement then add 1) **on an unsigned sized value** and still **result in an unsigned value** (a value that operands treat as unsigned)
- Ex: '-d8 is a 32-bit unsigned value storing a signed representation of (-8)
  This means that operations don't know to use signed arithmetic on the result, even though we might like to think of the bits as representing an signed representation
  - ('d8)/2 does not produce “-4” since ('d8) is unsigned and thus unsigned division is performed which does not preserve sign
  - -(d8)/2 does produce “-4”
integer int1, int2, int3, int4, int5, int6, int7;
initial begin
    int1 = -8; // 1111 1111 1111 1111 1111 1111 1111 1000
    int2 = -'d8; // 1111 1111 1111 1111 1111 1111 1111 1000
    int3 = -'d8/2; // 0111 1111 1111 1111 1111 1111 1111 1100
    int4 = -8/2; // 1111 1111 1111 1111 1111 1111 1111 1100
    int5 = int1/2; // 1111 1111 1111 1111 1111 1111 1111 1100
    int6 = int2/2; // 1111 1111 1111 1111 1111 1111 1111 1100
    int7 = -('d8/2); // 1111 1111 1111 1111 1111 1111 1111 1100
    int8 = -('d8)/2; // 0111 1111 1111 1111 1111 1111 1111 1100
end
One solution is the new signed sized literals using s in front of the format specifier to provide a signed type

- Ex: -'sd8 is a 32-bit signed value storing a signed representation of (-8)
  This means that operations do know to use signed arithmetic
    - (-'sd8)/2 does produce “-4” since (-'sd8) is signed and thus signed division is performed which does preserve sign
    - -(‘sd8)/2 does produce “-4”

- Ex:
  16'sh00A0; //16-bit signed +10
  -16'sh00A0; //16-bit signed -10
  16'shFFFF; //16-bit signed -1
integer int1,int2,int3,int4,int5,int6,int7;

initial begin
int1= -8; // 1111 1111 1111 1111 1111 1111 1111 1111 1000
int2= -'sd8; // 1111 1111 1111 1111 1111 1111 1111 1111 1000
int3= -'sd8/2; // 1111 1111 1111 1111 1111 1111 1111 1111 1100
int4= -8/2; // 1111 1111 1111 1111 1111 1111 1111 1111 1100
int5= int1/2; // 1111 1111 1111 1111 1111 1111 1111 1111 1100
int6= int2/2; // 1111 1111 1111 1111 1111 1111 1111 1111 1100
int7= -('sd8/2); // 1111 1111 1111 1111 1111 1111 1111 1111 1100
int8= (-'sd8)/2;// 1111 1111 1111 1111 1111 1111 1111 1111 1100
end
Reals

• Reals generally treated as double, 64 bit elements
• Literals may be provides in exponential (e.g. 1.2e-3) or basic decimal format (.34)
• No bit access
• No direct passing through ports of primitives or modules
• Use $realtobits,$bitstoreal, $rtoi (truncate), and $itor to convert to 64-bit binary and integers
• May be used to pass reals through 64-bit ports that are declared as follows:

```
module (output wire [63:0] realIn,
    input wire [63:0] realOut));
real tmp;
tmp = $bitstoreal(realIn);
realOut = $realtobits(tmp);
```
• time is a u64
• realtime is a real
• Like integer and real, these may not be used in a module port or be an output or input of a primitive
• Time is defined according to the time_unit and base provided by

```
timescale time_unit base / precision base
```

• time_unit is the time step represented by #1.0
• base is s, ms, us, ns, ps, or fs
• precision is the rounding precision of the simulation
• Example:

```
timescale 1ns/1ps
```
sets #1.0 to mean 1 ns delay
Checking `timescale

• If you want to print the timescale used in your simulation, you can print it using the following in your testbench or in other files.

  initial $printtimescale;

  Prints the following when place in module DUT_tb:
  Timescale of (DUT_tb) is 1ns/1ps.

• Checking other modules in the hierarchy can be done by providing the hierarchical name of the module:

  initial $printtimescale(DUT_tb.DUT.I4);
Time-related system tasks and functions

• Related system functions:
  • `$time` is a system function which provides an integer
  • `$stime` provides a truncated 32-bit time
  • `$realtime` provides a real (64-bit) time according
• In a format string for a system task like `$display`, use “%0t” to print time:
  • `$display("time is %0t",$time);`
%t follows a global default format that which can be redefined using the following system task:
  • `$timeformat(unit, precision, suffix, min_field_width);`
    • `unit` is a value from 0 to -15 representing seconds to femtoseconds
    • `precision` represents the number of decimal points to display
    • `suffix` is a string to append to what is printed (e.g. “ns”)
    • `min_field_width` represents the minimum number of characters to use to print time
Arrays

- A 2D bit memory can be defined with reg array
  Example:
  
  ```vhdl
  reg [31:0] cache_memory [1023:0]
  Defines 1024 32-bit entries
  ```

- Integer(32-bit) array
  ```vhdl
  integer cache_memory [1023:0];
  ```

- Real array
  ```vhdl
  real sin_table[1023:0];
  ```

- An array of time can be created:
  ```vhdl
  time T[1:00];
  ```

- Multi-dimensional arrays are allowed
  - Example:
    - ```vhdl
    reg [31:0] cache_memory [15:0][1023:0]
    16 banks of 1024 words of length 32 bits each,
    ```
    - ```vhdl
    cache_memory [15][1023][0] is the lsb of the last word
    ```
Strings

• no built in string/char type
• just reserve 8 bits per char in reg declaration

```verilog
class parameter numchar = 7;
reg [((8*numchar)-1):0] my_string;
my_string = "Hi";
```

Result is padded with 0s on left and no trailing 0/null:
```verilog```
my_string = 0 0 0 0 0 'H' 'I'
```verilog```
Constants may be stored and recalled with parameters, `localparam`

Parameters can be defined using keyword `localparam`. These are good way to store named constants (magic numbers), but be mindful of the automatic type being assigned.

```vhdl
localparam a=31; //int
localparam a=32,b=31; //ints
localparam byte_size=8, byte_max=byte_size-1; //int
localparam a =6.22; //real
localparam delay = (min_delay + max_delay) /2 //real
localparam initial_state = 8'b1001_0110; //reg
```
Arithmetic Operators

- Binary: +, -, *, /, % (the modulus operator)
- Unary: +, - (This is used to specify the sign)
- Integer division truncates any fractional part
- The result of a modulus operation takes the sign of the first operand
- Unlike bitwise operators, if any operand bit value is the unknown value x, then the entire result value is x (e.g. x*0 → x)
- Register data types are used as unsigned values (Negative numbers are stored in two's complement form)

```
5  +  10 =  15
5  -  10 =  -5
10 -  5  =   5
10 *  5  =  50
10 /  5  =  2
10 /  -5 = -2
10 %  3  =   1
+5       =  5
-5       =  -5
```
Unary Reduction Operators

- Unary Reduction operators
  - operate on one operand, produce single bit result
  - Operations with x and z bits may be resolvable (e.g. x and 0 = 0)

<table>
<thead>
<tr>

\end{align*}
\]
Logical Operators

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>negation</td>
</tr>
<tr>
<td>&amp;&amp;,</td>
<td></td>
</tr>
<tr>
<td>==,!=</td>
<td>Logical equality</td>
</tr>
<tr>
<td>===,!===</td>
<td>Case equality</td>
</tr>
</tbody>
</table>

- `===,!===` compare bit matching including x and z
- `==,!=` produce x if any x or z exists
- Left zero padding performed as needed
- Signed and unsigned integers and reals are converted to binary and treated as unsigned
- `&&` look for two non-zero valid words
- `||` looks for one non-zero, both valid words
- What about a non-valid bits?
  - `(3'b110 && 3'b11x) → (1 && 0) → FALSE=0`
  - `(3'b110 & 3'b11x) → (3'b110) → TRUE=1`
<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a === b</td>
<td>a equal to b, including x and z (Case equality)</td>
</tr>
<tr>
<td>a !== b</td>
<td>a not equal to b, including x and z (Case inequality)</td>
</tr>
<tr>
<td>a == b</td>
<td>a equal to b, result may be unknown (logical equality)</td>
</tr>
<tr>
<td>a != b</td>
<td>a not equal to b, result may be unknown (logical equality)</td>
</tr>
</tbody>
</table>

- Operands are compared bit by bit, with zero filling if the two operands do not have the same length
- Result is 0 (false) or 1 (true)
- For the == and != operators, the result is x, if either operand contains an x or a z
- For the === and !== operators, bits with x and z are included in the comparison and must match for the result to be true

Note: The result is always 0 or 1 unless result is unknown and x results...
Equality Examples

4'bx001 === 4'bx001 → 1
4'bx0x1 === 4'bx001 → 0
4'bz0x1 === 4'bz0x1 → 1
4'bz0x1 === 4'bz001 → 0
4'bx0x1 !== 4'bx001 → 1
4'bz0x1 !== 4'bz001 → 1

5 == 10 → 0
5 == 5 → 1
5 != 5 → 0
5 != 6 → 1
Bit-Wise Operators

• Bit-wise operators on pairs of operands
  • output same size as inputs
  • shorter binary operands are zero-padded on the left to the longer
  • these operators imply gates

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Operator</th>
<th>~4'b0001</th>
<th>~4'bx001</th>
<th>~4'bz001</th>
</tr>
</thead>
<tbody>
<tr>
<td>~</td>
<td>not/compliment</td>
<td>= 1110</td>
<td>= x110</td>
<td>= x110</td>
</tr>
<tr>
<td>&amp;</td>
<td>and</td>
<td>4'b0001 &amp; 4'b1001 = 0001</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>or</td>
<td>4'b1001 &amp; 4'bx001 = x001</td>
<td></td>
<td></td>
</tr>
<tr>
<td>^</td>
<td>xor</td>
<td>4'b0001 ^ 4'b1001 = 1000</td>
<td></td>
<td></td>
</tr>
<tr>
<td>~^</td>
<td>xnor</td>
<td>4'b0001 ^ 4'bx001 = x000</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

• Note x (z is treated same as x) is not always “contagious” if the operation makes the result unambiguous
• x&1'b0 → 0 and x|1'b1 → 1
Logical Operators

</tr>
</tbody>
</table>

- Expressions connected by && and || are evaluated from left to right (con1 && cond2 || cond3)
- Evaluation stops as soon as the result is known (short-circuit evaluation)
- The result is a scalar value:
  - 0 if the relation is definitely false
  - 1 if the relation is definitely true
  - x one of the operands is x and the result is undetermined by the operator and the other operand
Logic Negation, !Op

- Creates inverse of logic result
- For binary vectors, the operand Op must be converted to a “boolean” value OpLogic=1/0/x
  The process can be described like a statemachine involving an intermediate result OpLogic and a scan position
  - Start by assuming OpLogic=0
  - Search Operand vector left to right
    - if 0 found, don’t modify OpLogic, move inspection right
    - if 1 found, stop evaluation, operand is definitely True (OpLogic=1) and so result of logic 0
    - if x or z found, change OpLogic=x for now, continue inspection to the right
    - if end found,
      - if OpLogic is 1, result is 0
      - If OpLogic is x, result is x
- For integers, returns 1 for 0 and 0 otherwise

<table>
<thead>
<tr>

</table>
True if certainly non-zero, sure that a 1 exists

```plaintext
if (u2b) begin
    $display("True");
end else begin
    $display("Not True"); //though perhaps not false
end

u2b=2’b00    Not True
u2b=2’bxx    Not True
u2b=2’bx0    Not True
u2b=2’b0x    Not True
u2b=2’bz0    Not True
u2b=2’bz1    True
u2b=2’b1z    True
```
Relational Operators

- Nets and registers treated as unsigned words
- If any bit is unknown, the relation is unknown and result is ambiguous

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Operator</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>Less than</td>
</tr>
<tr>
<td>&lt;=</td>
<td>Less than equal to</td>
</tr>
<tr>
<td>&gt;</td>
<td>Greater than</td>
</tr>
<tr>
<td>&gt;=</td>
<td>Greater than or equal to</td>
</tr>
</tbody>
</table>

When one or both operands of a relational expression are unsigned, the expression shall be interpreted as a comparison between unsigned values. If the operands are of unequal bit lengths, the smaller operand shall be zero-extended to the size of the larger operand. --IEEE Spec
# Implicit Casting Surprises

- Mix of unsigned and signed results in unsigned cast examples for $W=32$

**Conditional ? Operator**

• **Syntax:**
  - `Conditional_expression := selection_expression ? true_expression : false_expression`

• **Can use in continuous assign statements and in procedural blocks**

```vhdl
Y = (sel) ? A:B;
count = (c>threshold) ? count : count-1;
Y = (A>B) ? A:B;  //max of A and B
```

Like **if**, ? is conceptually a mux;
Note: z **CAN** be passed through expressions to the output
if selection expression is unambiguous 1 or 0

```vhdl
Y = (en) ? data:16'b0z;  en=x gives unknown but
    en=1 will pass data and
    en=0 will pass multiple z bits
```

This is sometimes the recommended coding for synthesizing a tristate buffer.
Conditional ? Operator

- Z not allowed in conditional_expression
- Zeros are automatically filled for different length operands
- If conditional_expression is ambiguous, both true_ex and false_ex are evaluated and result is calculated on a bitwise basis according to truth table below (same as collision of wires, exists since section doesn't matter if both bits are same)

<table>
<thead>

Concatenation and Repetition Operator

- Concatenation operator can create a single word from two or more operands
- Useful for forming logic buses
- Concatenation follows order given
- Nesting allowed

\[
\begin{align*}
\{2'b'01, 3'b010\} & \rightarrow 5'b01010 \\
\{4\{2'b01\}\} & \rightarrow \{2'b01, 2'b01, 2'b01, 2'b01\} \rightarrow 8'b01010101 \\
\{4'b0001, \{\{2'b01\}, \{2'b10\}\}\} & \rightarrow 8'b00010110
\end{align*}
\]

No operand may be an unsigned constant since compiler would not be able to size the result

**Repetition operator** should be used with a constant repetitions:

\[
4\{2b'01\} \rightarrow 8'b01010101
\]

- Left-most bit is extended as required to fill bits.
Working with signed and unsigned reg and wire

Verilog 2001 provides signed reg and wire vectors

Casting to and from signed may be
  implicit
  or may be
  explicit by using
    $unsigned()  reg_s=$unsigned(reg_u);
    $signed()    reg_u=$unsigned(reg_s);

Implicit and Explicit Casting is always a **dumb conversion** (same as C), they never change bits, just the interpretation of the bits (e.g. -1 is not round to 0 upon conversion to unsigned, it is just reinterpreted as the largest unsigned value) for subsequent operations
If a mix of signed and unsigned operands are provided to an operator, both operands are first cast to be unsigned (like C).

Signed/Unsigned Casting may be followed with length adjustment. Assignment to a shorter type is always just bit truncation (no smart rounding such as unsigned(-1) → 0).

• Error Checking
  • For unsigned, truncation is no problem as long as all the truncated bits are 0.
  • For signed, truncation is no problem as long as all the bits truncated are the same AND they match the surviving msb.

Assignment to a longer type is done with either zero or sign extension depending on the type:
  • Unsigned types use zero extension
  • Signed types use sign extension
Rules for expression bit lengths

A self-determined expression is one in which the length of the result is determined by the length of the operands or in some cases the expression has a predetermined length for the result.

Example: as self-determined expression the result of addition has a length that is the maximum length of the two operands.

Example: a comparison is always a self-determined expression with a 1-bit result.

However, addition and other operation expressions may act as a context-determined expression in which the bit length is determined by the context of the expression that contains it.
Addition

Two's compliment addition of two numbers where the longest is N-bit can require up to N+1 bits to store a full result.

Two's compliment addition can only overflow if the signs of the operands are the same.
- The error check is to see if the new sign bit is the same as the old.

Two's compliment subtraction can only under/overflow if the signs of the operands are different.
- The error check is to see if the sign bit of the second and third operand are the same and not equal to that of the first.
In this example we see that addition obeys modular arithmetic with a result $u8y=0$

```c
ur8a = 128;
ur8b = 128;
ur8y = ur8a+ur8b;
```

In this example we see that the addition is an expression paired with an assignment, so the length of the assigned variable sets the context-determined expression operand length of the addition to take on the length of the largest operand, 9-bits. Using zero-extension in this case, the addition operands are each extended to 9-bits before addition.

The result is $u9y=256$

```c
ur8a = 128;
ur8b = 128;
ur9y = ur8a+ur8b; // 9-bit addition
```
Self-Determined Expression and Self-Determined Operands

- Some operators always represent a self-determined expression, they have a well-defined bit-length that is independent of the context in which they are used and must be derived directly from the input operand(s) (the result may still be extended or truncated as needed). These may also force the operands to obey their self-determined expression bit length.

- The concatenation operator is one such example of a self-determined expression with a bit-length that is well-defined as the sum of length of its operands, and in turn its operands are forced to use their self-determined expression length.
  
  Single-operand: e.g. `{a}` for which the result is the length of `a`
  Multiple operands: e.g. `{2'b00,b,a}` for which the result length is 2+length(b)+length(a)

- The use of a single operand `{}` can force a self-determination for expressions like addition:

- In this next example, the self determined length of the addition is 8-bits which results in 0 for the summation. The 8-bit result from the concatenation operator is always unsigned and thus is zero extended.

```plaintext
ur8a = 128;
ur8b = 128;
ur16y = {ur8a+ur8b};  // 8 bit addition
ur16z = ur8a+ur8b;   // 16 bit addition
```
5.4.1 Rules for expression bit lengths
The rules governing the expression bit lengths have been formulated so that most practical situations have a natural solution.

The number of bits of an expression (known as the size of the expression) shall be determined by the operands involved in the expression and the context in which the expression is given.

A self-determined expression is one where the bit length of the expression is solely determined by the expression itself—for example, an expression representing a delay value.

A context-determined expression is one where the bit length of the expression is determined by the bit length of the expression and by the fact that it is part of another expression. For example, the bit size of the right-hand expression of an assignment depends on itself and the size of the left-hand side.

Table 5-22 shows how the form of an expression shall determine the bit lengths of the results of the expression. In Table 5-22, i, j, and k represent expressions of an operand, and L(i) represents the bit length of the operand represented by i.

Multiplication may be performed without losing any overflow bits by assigning the result to something wide enough to hold it.

</table>

\(^a\)If an unsized constant is part of an expression that is longer than 32 bits and if the most significant bit is unknown (X or x) or three-state (Z or z), the most significant bit is extended up to the size of the expression. Otherwise, signed constants are sign-extended and unsigned constants are zero-extended.

Search for

IEEE Std 1364-2005

You'll find

Along with the older standard 1995 standard and the SystemVerilog standard
reg [3:0] bottleStock = 10; //unsigned

always @(posedge clk, negedge rst_)
  if (rst_==0)
    bottleStock<=10;
  else if (bottleStock >= 0) //always TRUE!!
    bottleStock <= bottleStock-1;
input wire [2:0] remove;
signed reg [3:0] remainingStock = 10; //signed

always @ (posedge clk, negedge rst_)
  if (rst_ == 0)
    remainingStock <= 10;
  else if ((remainingStock - remove) >= 0) //always TRUE!!!
    remainingStock <= remainingStock - remove;
Scaling

Multiplication by positive integers may be performed with the shift operator if by a power of two:
Mult by $2^k$ is left shift by $k$

$$a \ll k$$

Typically synthesizers require $k$ to be a constant;
k bits on left are discarded

Detecting Overflow: no overflow if all truncated bits are the same and the new msb matches the truncated bits

Logical Shifting is usually inexpensive – just “rewiring”.
Multiplication by numbers with a few non-zero bits can be inexpensive as well:

$$u \times 24 = u \ll 4 + u \ll 3$$

This is an important tool for computer engineering to know.
Divide by power of two

Divide by $2^k$ is nearly arithmetic right shift
Need to Discard $k$ bits on the right and replicate sign bit $k$ times on the left. Must use the arithmetic shift;

    a>>>k;  same as  {k{a[msbindex]},a[msbindex:k]}

However, by definition integer division truncates the fractional bits of the result.
This is also known as “round towards zero”
For a positive number this is floor($x/n$)    5/2=2
For a negative number this is ciel($x/n$)    -5/2=-2

If number is positive just use    a>>k;

For a negative number, we want
ciel($x/n$) which may be computed using an offset that is half the divisor:
floor((x+2^{k-1})/2^k))

In verilog: (a+(1<<k)) >>> k
Rounded Integer Division

- Rounded-result division may be accomplished by adding an offset to the operand that is half the magnitude of the divisor (truncated to an integer) and matches the sign of the operator.

- Try to make code to divide a signed integer, S, by 256 with a rounded result:
  \[
  \text{result} = (S \geq 0) ? \frac{(S+128)}{256} : \frac{(S-128)}{256};
  \]

- Try to make code to divide a signed integer, S, by 5 with a rounded result:
  \[
  \text{result} = (S \geq 0) ? \frac{(S+2)}{5} : \frac{(S-1)}{5};
  \]

- A synthesizer may only support division by powers of two and possibly only constants.
Multiplication

In general to hold the result you need M+N bits where M and N are the length of the operands

```plaintext
wire [N-1:0] a;
wire [M-1:0] b;
wire [M+N-1:0] y;

y = a * b;
```

The multiplication in the context with the assignment will cause extension of operands to the size of the result.
